Significance

The global population is aging, driving up age-related disease morbidity. Antiaging interventions are needed to reduce the burden of disease and protect population productivity. Young people are the most attractive targets for therapies to extend healthspan (because it is still possible to prevent disease in the young). However, there is skepticism about whether aging processes can be detected in young adults who do not yet have chronic diseases. Our findings indicate that aging processes are detectable in people still young enough for prevention of age-related disease. The science of healthspan extension must focus on the end of the lifespan; rather than only studying old humans, get to know the young.

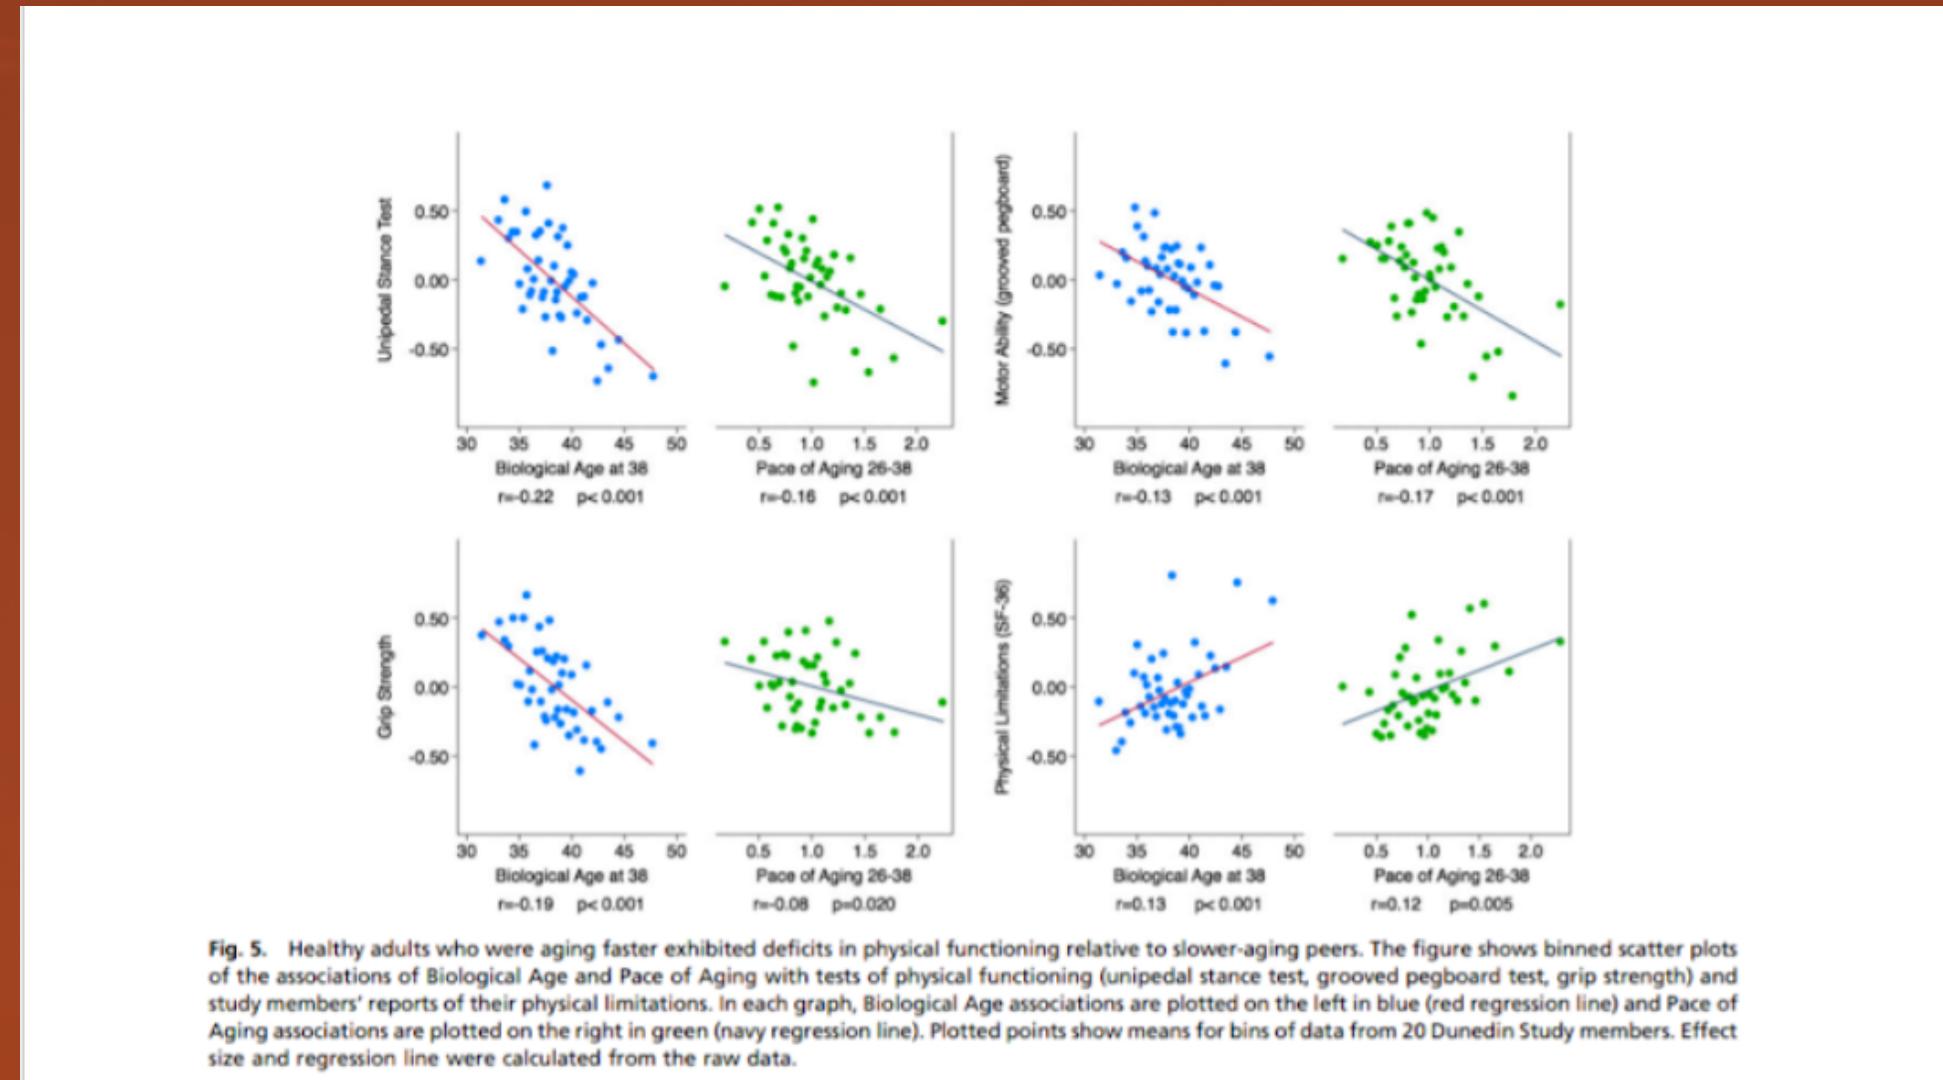

Biological Age	Percent
30	~0.5%
31	~1.5%

Kaç yaşındasın?

Çalışmalar bedenin yaşının kronolojik göstergelerden bağımsız olabileceğini gösteriyor

- Çalışmadaki 1000 kişi, 38 yaşında
- Biyolojik yaşıları: 25-50

Biyolojik yaş - fiziksel görünüm ve beden işlevleri ile daha uyumlu

Biyolojik yaşlanma eğrileri

Yaşlanma hızı kişiye özgü

Bazı deneklerin yaşlanma hızı 16 sene boyunca sıfırı yakın izlemiş

Az sayıda denegenin 16 senelik izlemde biyolojik yaşıının azalmış

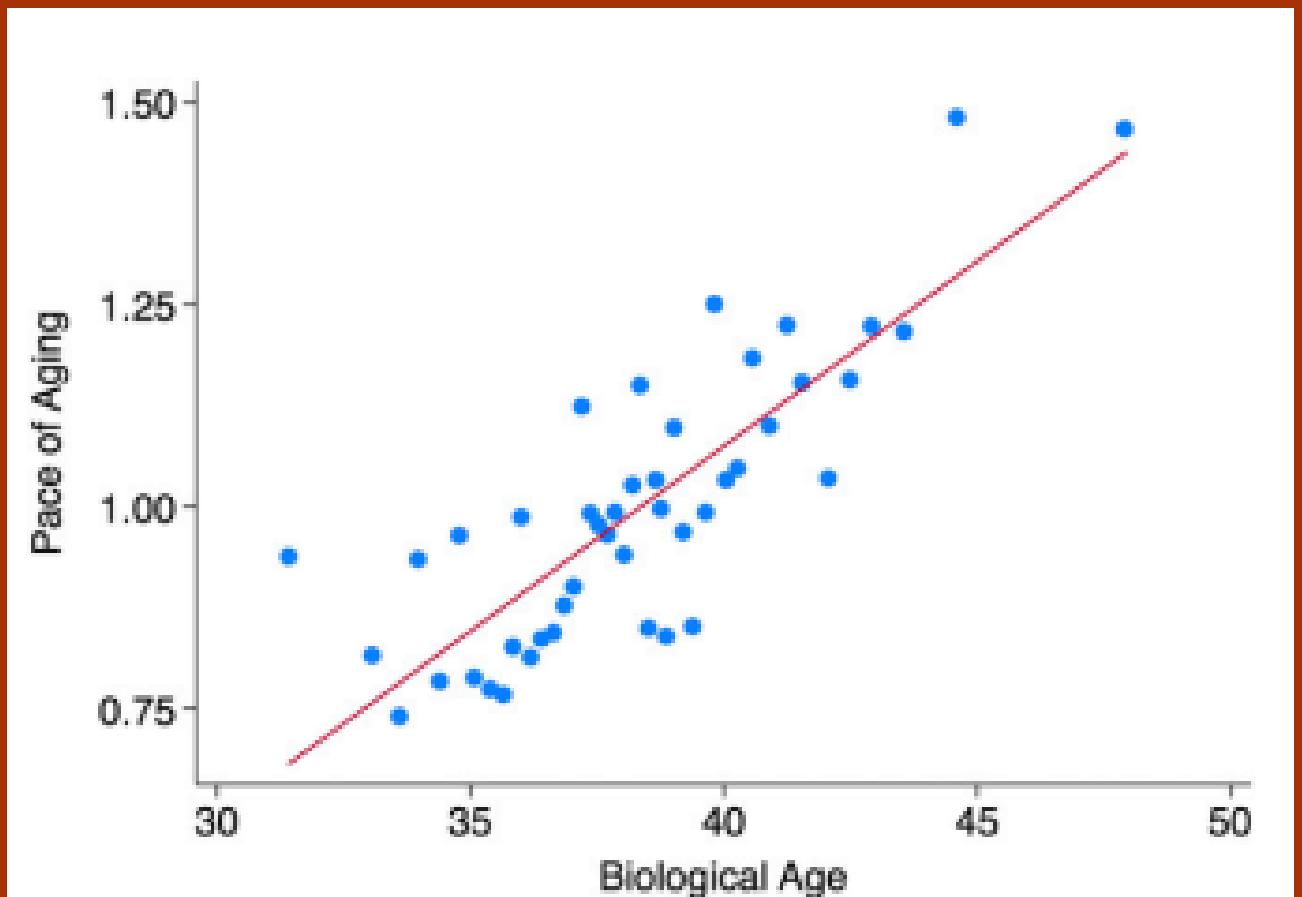

Fig. 4. Dunedin Study members with older Biological Age at 38 y exhibited an accelerated Pace of Aging from age 26–38 y. The figure shows a binned scatterplot and regression line. Plotted points show means for bins of data from 20 Dunedin Study members. Effect size and regression line were calculated from the raw data.
